Lab 5 – Network Topology Visualization (Visio)

February 24, 2026

Lab Questions

1. Can a user workstation directly access the database server? Why or why not?

No, a user workstation can't access the database server, as the database server is restricted to only allow traffic from the application server.

2. Where are the main security enforcement points in your network?

The edge firewall and the core switch are the main security enforcement points in the network. The edge firewall controls all traffic that go into the network from the internet and the DMZ as well as all traffic out to the DMZ and the internet from the network. It will also contain all of the ACLs and other security policies and act as the router in the network. The core switch will contain all of the VLAN data, keeping the network segmented.

3. If a workstation becomes compromised, what systems could it potentially reach?

According to how the network is segmented, the non-admin's work stations have access only to the web server and, theoretically, the other workstations on the same VLAN. With proper ACLs, the access from any workstation should be limited to the permissible traffic to and from the web server.

4. What is the most critical system in your design and why?

The most critical system in my design is the ASA Firewall. Its secure configuration is key to ensuring that each security zone remains isolated. Implementing a least privilege standard will also help to ensure that no one system or endpoint can access more than the least amount possible to successfully perform its job.
