

1. Create a python script file called post.py (10 points)
 - a. Using the api that this site offers, <https://reqres.in/>, create a new user (look for the box that says “Post” with “Create” underneath it. If you click on it, it will provide the documentation of what the url you should hit and the payload it expects.
 - b. Call that api and create a user named “John Doe” with a job of “Private Detective”
 - c. Capture the response to the api as a variable called “response”
 - d. If the response (status) code is 201, print the return text from the api
 - e. If the response isn’t a 201, print:
 - i. “API call failed with reason: <reason provided by api>”
 1. <reason provided by api is an attribute from the api response
2. Create a python script file called dogs.py (20 points)
 - a. Using the “list all breeds” api offered here, <https://dog.ceo/dog-api/documentation/>, create a function called “list_breeds” which returns a list called “dog_breeds” that contains all the breeds (don’t worry about subbreeds, just do breeds) available
 - b. Using the “Random Image From a Breed Collection” under the “By Breed” endpoint (second example if you scroll down) api offered her, <https://dog.ceo/dog-api/documentation/>, create a function called “get_random_dog_pic”
 - i. This function should take in the name of a dog breed
 - ii. Make a request to the api to get a random picture
 - iii. Open the random picture using the webbrowser library (look at docs or review doggo.py example shown during lecture)
 - c. When the script is executed, it should do the following:
 - i. Call the “list_breeds” function and set its return equals to a variable
 - ii. Ask for input using the following message:
 1. What breed of dog would you like to see a picture of?
 - iii. Check if the breed provided is in list of breeds that the api has pictures for
 1. You should make sure you convert the input to all lower case since all the breeds in the api are lowercase
 2. If the breed is supported by the api, you should call the “get_random_dog_pic” function using the breed requested via input (again, remember to convert this value to all lowercase)
 3. If it isn’t supported, print the following statement:
 - a. Sorry, we don't have pictures of that breed
 - iv. Ask the user if they want to continue, if they do you should loop over the above logic again... If not, exit the program.
